

# Pandas cheatsheet 1

Import	Selection	Sorting
<code>import pandas as pd</code>	<b>return one column</b> <code>df['column name']</code>	<b>sort (by one column)</b> <i>sorting can be done column wise – default is ascending</i> <code>df.sort_values(by='col name')</code>
Reading and Saving csv	<b>return multiple columns</b> <code>df[['column1', column2]]</code>	<i>use ascending=False for descending sort - "by=" may be omitted</i>  <code>df.sort_values('col1', ascending=False)</code>
<code>pd -&gt; pandas</code> <code>df -&gt; dataframe</code>  <b>to read a file into dataframe</b> <code>df = pd.read_csv('filename')</code>	<b>return one line</b> <code>df.loc[4]</code>	<b>sort by multiple columns</b> <code>df.sort_values(['col1', 'col2'], ascending = [True,False])</code>
<b>to save a dataframe to a file</b> <code>df.to_csv('filename')</code>	<b>return multiple lines</b> <code>df.loc[[4,8]]</code>	
Describing dataframe	<b>return a range of lines</b> <code>df.loc[4:8]</code>	
<b>look at the first 5 lines</b> <code>df.head()</code>	<b>return a cell</b> <code>df.loc[4, 'col name']</code> <code>df.loc[4]['col name']</code>	Filtering
<b>look at the last 5 lines</b> <code>df.tail()</code>	<b>return a range of lines and columns</b> <code>df.iloc[0:4, 1:3]</code>	<b>filtering with one condition</b> <i>return rows where the condition is True</i> <code>df[df['col1'] &gt;= 5]</code>
<b>to get the dimensions of df</b> <code>df.shape</code>	Statistics (column with nums)	<b>filtering with two conditions</b> <i>with "&amp;" both conditions must be True</i> <code>df[(df['col1'] &gt;= 5) &amp; (df['col2'] != "Asia")]</code>
<b>to print all the column names</b> <code>df.columns</code>	<b>median (διάμεσος)</b> <code>df['population'].median()</code>	<i>with " " either condition must be True</i> <code>df[(df['col1'] &gt;= 5)   (df['col2'] != "Asia")]</code>
<b>to print data types</b> <code>df.dtypes</code>	<b>mean (μέση τιμή)</b> <code>df['population'].mean()</code>	
<b>to describe df</b> <code>df.describe()</code>	<b>sum</b> <code>df['population'].sum()</code>	Grouping
Describing columns	<b>minimum value</b> <code>df['population'].min()</code>	<b>get information about subsets</b> <i>e.g. group rows with the same values in a column and get the mean of the corresponding values from another column</i> <code>df.groupby("continent")["gdp_per_capita"].mean()</code>
<b>unique values in a column</b> <code>df['column name'].unique()</code>  <i># if no spaces we can omit [""]</i> <code>df.column_name</code>	<b>maximum value</b> <code>df['population'].max()</code>	
<b>describe (results depend on variable type)</b> <code>df['column name'].describe()</code>	<b>standard deviation (τυπική απόκλιση)</b> <code>df['population'].std()</code>	Df manipulation
<b>value counts (frequencies)</b> <code>df['col name'].value_counts()</code>	<b>correlation (συσχέτιση)</b> <code>df['population'].corr()</code>	<b>create a new column</b> <code>df['newCol'] = df['col3'] / 5</code>
		<b>create a new dataframe</b> <code>df2 = df[['c4', 'c1', 'c2']]</code>
